# Disappointment & Hope

Because.....

All recent trials failed to improve CV and renal outcomes in patients with type 2 diabetes mellitus

But .....

More than 50.000 patients are currently in clinical trials that will report renal outcome data from 2015 onwards

# The diabetes epidemic: global projections for 2013–2035

# Estimated national prevalence of diabetes mellitus in selected Asia-Pacific region countries

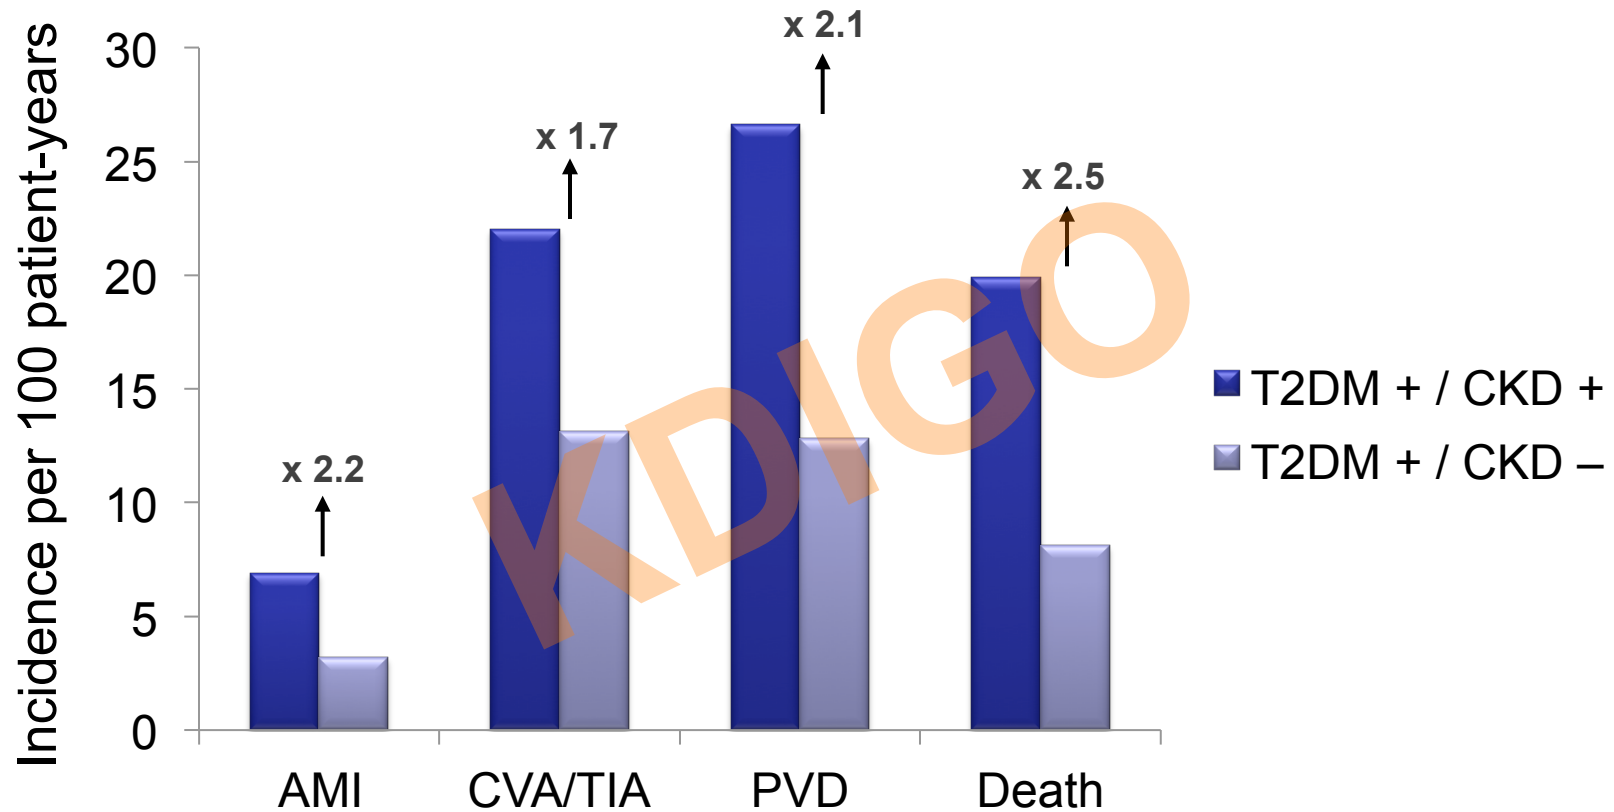

# Diabetes complications

# Cardiovascular risk is greatest when both diabetes and CKD are present

Among patients with diabetes and CKD, the rate of cardiovascular events is more than twice that among patients with diabetes only

# Impact of nephropathy on risk of death

# Diabetic nephropathy

- Leading cause of ESRD  
~ 30-50% of new cases
- Increasing prevalence globally
- Approximately one-third of all patients
- More common in Hispanics, Blacks and Native Americans
- High cardiovascular morbidity and mortality
- Cause incompletely understood and.... **No cure**

# The use of Metformin

A Cochrane review (347 trials & cohort studies) found no cases of lactic acidosis; half of the studies included CKD patients.

Metformin use should be re-evaluated when  $\text{GFR} < 45 \text{ ml/min/1.73m}^2$  (max 1000 mg) and stopped when  $< 30 \text{ ml/min/1.73m}^2$

The major precipitating factor is an abrupt loss of tubular secretion. Such a loss does not occur in stable CKD, but in AKI or rapid volume depletion associated with an intercurrent illness.

Patients with CKD should be alerted to withhold metformin if they experience intercurrent illness that could lead to rapid volume depletion.

# SAVOR-TIMI 53: study design

## SAVOR-TIMI 53

# SAVOR-TIMI 53: primary endpoint

The primary endpoint (CV death, nonfatal MI, nonfatal stroke)

## A Primary End Point

The upper limit of the 95% CI was  $<1.3$  but not  $<1.0$ . Therefore, saxagliptin met the non-inferiority criterion (did not increase the risk of CV events versus placebo) but did not demonstrate superiority (did not reduce the risk for CV events versus placebo).

### No. at Risk

Placebo	8212	7983	7761	7267	4855	851
Saxagliptin	8280	8071	7836	7313	4920	847

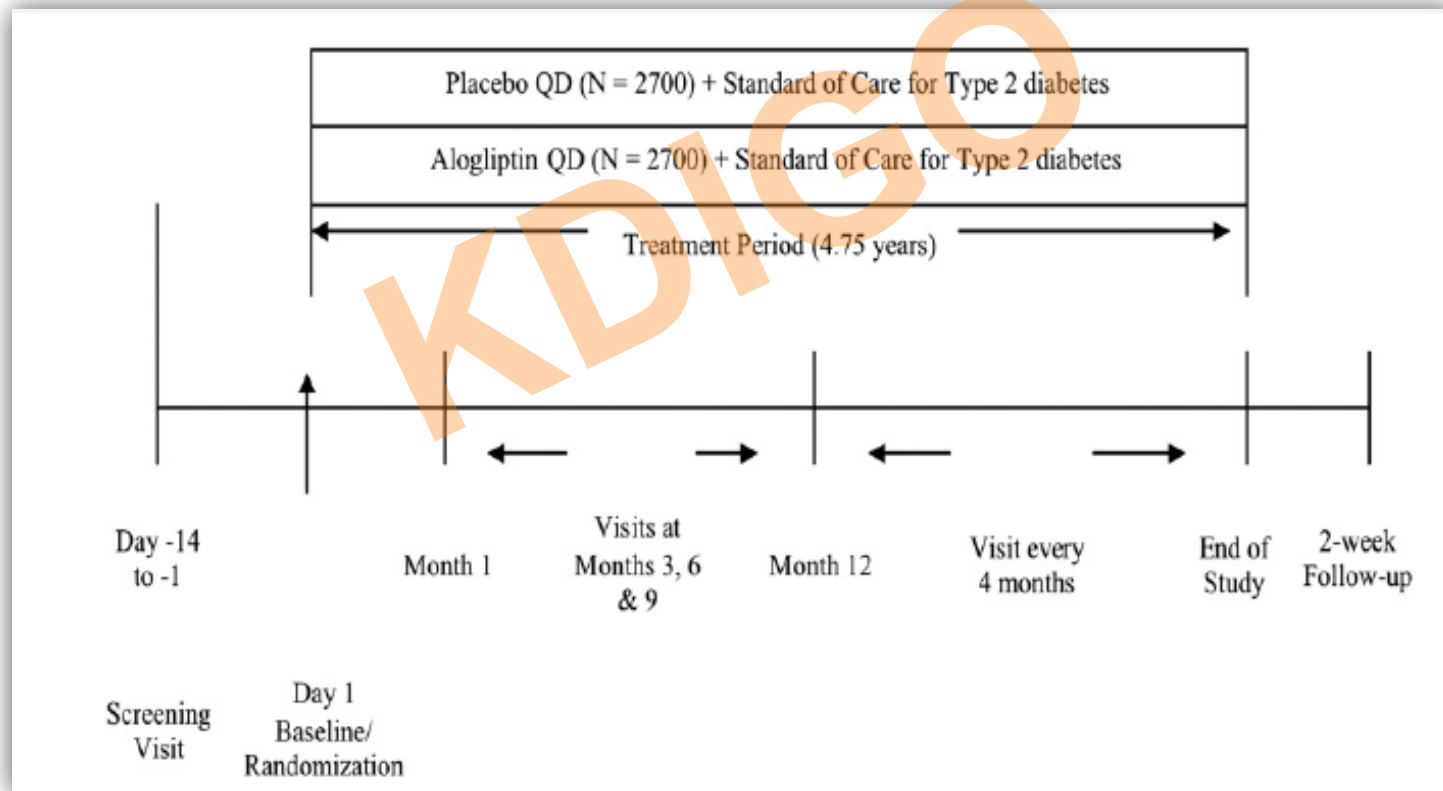

NEJM 2013;369:1317-2

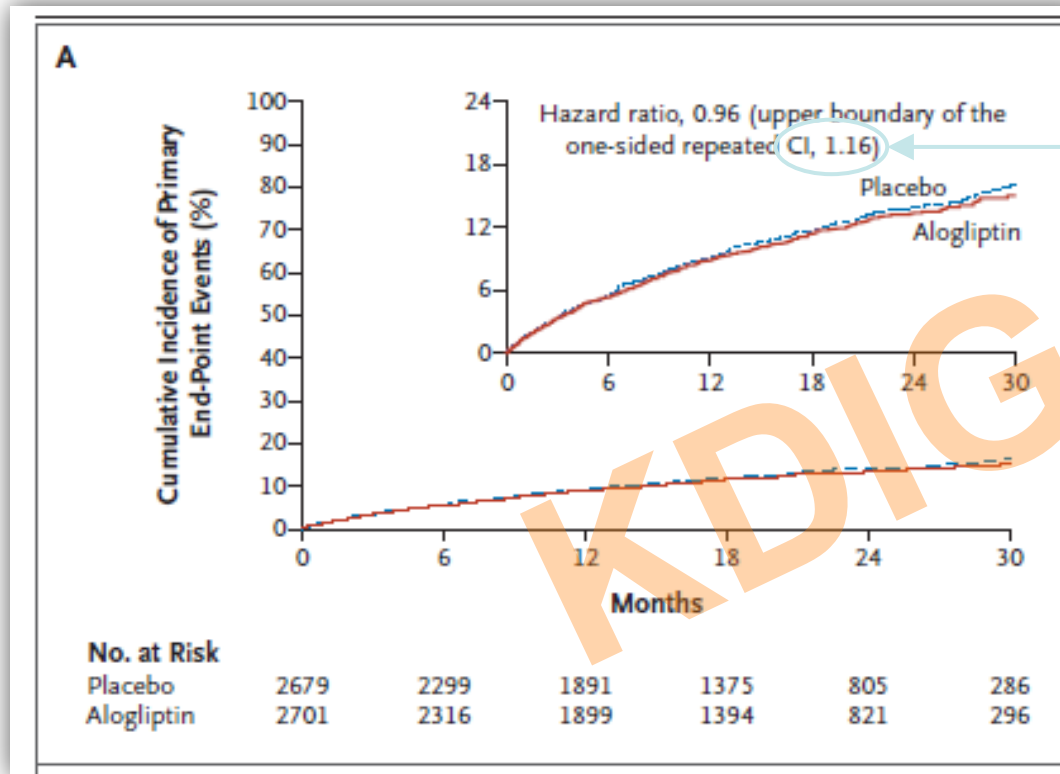

Kidney Disease

# EXAMINE: study design

Alogliptin versus placebo, in addition to standard of care, in subjects with type 2 diabetes mellitus, HbA1c 6.5–11.0%, and acute coronary syndrome (within 15-90 days prior to randomization)

# EXAMINE: primary endpoint

The upper limit of the HR was  $<1.3$ , which was the pre-specified safety boundary based on the FDA's 2008 guidance for evaluating CV safety of new antidiabetes drugs. Therefore, alogliptin met the non-inferiority criterion (did not increase the risk of CV events versus placebo). However, as the limit was not  $<1.0$ , alogliptin did not demonstrate superiority (did not reduce the risk for CV events versus placebo).

The primary endpoint (CV death, nonfatal MI, nonfatal stroke) occurred in 11.3% of alogliptin patients and 11.8% of placebo patients; hazard ratio=0.96 (one-sided repeated CI bound, 1.16)

CCRX Inhibition (Spiegelmer)

# Summary

- Worldwide epidemic of type 2 diabetes
- Aggressive multi-risk factor intervention including tight glycemic control improves outcomes
  - Microvascular
  - Macrovascular (not so much)
- Guidelines recommend tighter control of glycemia, but ...
- Renal endpoints critically important for newer therapies
- Regulatory agencies establish guidance for safety

Thank you
